RECURSION

- A process in which a function calls itself directly or indirectly is called ***recursion***
- The function that is repeatedly called is known as ***recursive function***
- Example:
 - ```
def countdown(n):
 if(n <= 0):
 print("Blastoff!")
 else:
 print(n)
 countdown(n - 1)
```
  - In main program, let's say we call the function countdown with argument 3  
i.e. `countdown(3)`

- Call countdown(3) from this main function
- 
- ```
graph TD; A[Call countdown(3) from this main function] --> B["The function is called with n = 3<br/>Checks n <= 0? No, so goes to 'else'<br/>In else block, it prints n which is 3 so it prints 3<br/>Calls itself with n - 1 = 3 - 1 = 2"]; B --> C["The function is called with n = 2<br/>Checks n <= 0? No, so goes to 'else'<br/>In else block, it prints n which is 2 so it prints 2<br/>Calls itself with n - 1 = 2 - 1 = 1"]; C --> D["The function is called with n = 1<br/>Checks n <= 0? No, so goes to 'else'<br/>In else block, it prints n which is 1 so it prints 1<br/>Calls itself with n - 1 = 1 - 1 = 0"]; D --> E["The function is called with n = 0<br/>Checks n <= 0? Yes, so goes to 'if'<br/>In if block, it prints Blastoff!<br/>After which the function ends, so return to where it was called from"]; E --> F["Comes back to the iteration that was run with n = 1<br/>Nothing else is left to do in the function<br/>Return to where it was called from"]; F --> G["Comes back to the iteration that was run with n = 2<br/>Nothing else is left to do in the function<br/>Return to where it was called from"]; G --> H["Comes back to the iteration that was run with n = 3<br/>Nothing else is left to do in the function<br/>Return to where it was called from"]; H --> I["Comes back to the main function and performs the next task if any"];
```

- The function is called with $n = 3$
- Checks $n \leq 0$? No, so goes to "else"
- In else block, it prints n which is 3 so it prints 3
- Calls itself with $n - 1 = 3 - 1 = 2$

- The function is called with $n = 2$
- Checks $n \leq 0$? No, so goes to "else"
- In else block, it prints n which is 2 so it prints 2
- Calls itself with $n - 1 = 2 - 1 = 1$

- The function is called with $n = 1$
- Checks $n \leq 0$? No, so goes to "else"
- In else block, it prints n which is 1 so it prints 1
- Calls itself with $n - 1 = 1 - 1 = 0$

- The function is called with $n = 0$
- Checks $n \leq 0$? Yes, so goes to "if"
- In if block, it prints Blastoff!
- After which the function ends, so return to where it was called from

- Comes back to the iteration that was run with $n = 1$
- Nothing else is left to do in the function
- Return to where it was called from

- Comes back to the iteration that was run with $n = 2$
- Nothing else is left to do in the function
- Return to where it was called from

- Comes back to the iteration that was run with $n = 3$
- Nothing else is left to do in the function
- Return to where it was called from

- Comes back to the main function and performs the next task if any

RECURSION

- Output?

RECURSION

- Example:
 - ```
def print_n(s, n):
 if(n <= 0):
 print("The End!")
 else:
 print(s)
 print_n(s, n - 1)
```
  - In main program, let's say we call the function:  
i.e. `print_n("Hello", 4)`
- Output?

# RECURSION

- Example:
  - Determine the sum of first “n” natural numbers

# RECURSION

- Example:
  - ```
def add_n(n):  
    if(n <= 1):  
        return 1  
    else:  
        next = add_n(n - 1)  
        return (n + next)  
        #return(n + add_n(n - 1))
```
 - In main program, let's say we call the function:
i.e. `add_n(10)`
- Output?

RECURSION

- Base Condition:
 - A base case solution added to recursive functions
 - If no base case specified, it won't know where to stop
 - Usually chosen as the smallest and most obvious condition
 - Recursive functions usually work backwards

STACKS

- A collection of objects that are inserted and removed using the Last-In-First-Out (LIFO) approach
- Can insert elements in stack at any time
- Remove the elements ONLY from top of the stack

FUNCTION FRAMES

- A frame is like a box with the function name besides it and all parameters and/or variables are inside it
- Every time a function is called, it creates a frame of the function and save it on stack, including the main function

Figure 5.1: Stack diagram.

FUNCTION FRAMES

- Example:
 - Draw a stack diagram for `print_n` called with `s = "Hello"` and `n = 2`

INFINITE RECURSION

- Either no base case present, or base case never reached
- It will continue making recursive calls forever and the program never terminates
- For example:
 - ```
def recurse():
 statement(s)
 ...
 recurse()
```
- Many program environments do not actually run forever to prevent any errors
- Generates an error message after stack is filled to its limit completely

# RECURSION EXAMPLE # 1

- Write a function to find Fibonacci series of n numbers, where  $n > 2$ , i.e. **0, 1, 1, 2, 3, 5, 8, 13, 21, ...**
- ```
def fib(n):  
    #Base conditions  
    if (n == 1):  
        return 0  
    elif (n == 2):  
        return 1  
    else:  
        return (fib(n - 1) + fib(n - 2))
```

RECURSION EXAMPLE # 1

- Main program

- `n = 5`

- `print("Fibonacci of " + n + " numbers is: ", end = " ")`

- `for i in range(0, n):`

- `print(fib(i), end = " ")`

- Output = ?

RECURSION EXAMPLE # 2

- Write a function that calculates Factorial value of n using recursion, where $n > 2$
- ```
def fact(n):
 #Base conditions
 if (n == 0 or n == 1):
 return 1
 else:
 return (n * fact(n - 1))
```

# RECURSION EXAMPLE # 2

- Main program
  - $n = 5$   
    `print("Factorial of " + n + " is:", str(fact(n)))`
- Output = ?

# RECURSION EXAMPLE # 2

- `def fact(n):`  
    #Base conditions  
    if (n == 100):  
        return 1  
    else:  
        return (n \* fact(n - 1))
- Output → ?
- Wrong base case which may cause stack overflow

# RECURSION EXAMPLE # 3

- Write a function that calculates  $\log_2 n$  using recursion, where  $n > 1$
- ```
def logbase2(n):  
    #Base condition  
    if (n == 1):  
        return 0  
    else:  
        return (1 + logbase2(n//2))
```

RECURSION EXAMPLE # 3

- Main program
 - `n = 15`
`print("Log base 2 of " + n + " is:", str(logbase2(n)))`
- Output = ?

RECURSION EXAMPLE # 4

- Write a function that prints octal equivalent value of decimal number, n using recursion, where $n \geq 0$
- ```
def dectooct(n):
 #Base condition
 if (n == 0):
 print("", end = "") #empty strings not even blank spaces
 else:
 dectooct(n//8)
 print(n%8, end="")
```

# RECURSION EXAMPLE # 4

- Main program
  - $n = 45$   
  `dectoact(n)`
- Output = ?

# RECURSION EXAMPLE # 5

- Write a function that calculates the power of 2 for “n” value using recursion, where  $n \geq 0$
- ```
def powerof2(n):  
    #Base condition  
    if (n == 0):  
        return 1  
    else:  
        val = 2 * powerof2(n - 1)  
        return val
```

RECURSION EXAMPLE # 5

- Main program
 - $n = 4$
print("The result of 2 to the power of ", n, "is:", powerof2(n))
- Output = ?

RECURSION EXAMPLE # 6

- Write a recursive function named `sum_odd` that takes two parameters `a` and `b` and returns the sum of all odd numbers between `a` and `b` inclusive
- ```
def sum_odd(a,b):
 if (b < a):
 return 0
 else:
 if (b % 2 == 0):
 return(sum_odd(a,b - 1))
 else:
 return(sum_odd(a,b-2) + b)
```

# RECURSION EXAMPLE # 6

- Main program
  - $a = 4, b = 10$   
`print(sum_odd(a,b))`
- Output = ?
